

# Using RQT, an R package for gene-level meta-analysis

Ilya Y. Zhbannikov

December 10, 2016

## 1 Overview

Despite the recent advances of modern GWAS methods, it still remains an important problem of addressing calculation an effect size and corresponding p-value for the whole gene rather than for single variant. We developed an R-package `rqt`, which offers gene-level GWAS meta-analysis. The package can be easily included into bioinformatics pipeline or used as stand-alone. Contact: [ilya.zhbannikov@duke.edu](mailto:ilya.zhbannikov@duke.edu) for questions of usage the `rqt` or any other issues.

Below we provide several examples that show GWAS meta-analysis on gene-level layer.

### 1.1 Methods in brief

The workflow of gene-level meta analysis consists of the following steps: (i) reducing the number of predictors, thereby alleviating correlation problem in variants (accounting for LD); (ii) then the regression model is fitted on the reduced dataset to obtain corresponding regression coefficient ("effect sizes"); (iii) these coefficients are then to be pooled into a total index representing a total gene-level effect size and corresponding statistics is calculated. P- and q- values are then calculated using this statistics from asymptotic approximation or permutation procedure; (iv) the final step is combining gene-level p-values calculated from each study with Fisher's combined probability method.

## 2 Data description

### 2.1 Single dataset

In `rqt` requires the following datasets: (i) **phenotype** (a  $N$  by 1) matrix (i.e. a vector); and (ii) **genotype** - an object of class `SummarizedExperiment` containing one assay: (a  $N$  by  $M$ ) matrix, where  $N$  - is the total number of individuals in the study and  $M$  is the total number of genetic variants. Optionally, `rqt` can accept covariates, in form of  $N$  by  $K$  matrix, where  $K$  is the total number of covariates used in the study. Phenotype can be dichotomous (0/1, where 1 indicates control and 0 case).

### 2.2 Meta-analysis

In meta-analysis, `rqt` requires a list of  $M$  ( $M$  - number of datasets used in meta-analysis) and optionally it accepts covariates in form described above.

### 3 Examples

#### 3.1 Gene-level analysis on a single dataset

#### 3.2 Dichotomous phenotype

```
> library(rqt)
> data <- data.matrix(read.table(system.file("extdata/test.bin1.dat",
+                                           package="rqt"), header=TRUE))
> pheno <- data[,1]
> geno <- data[, 2:dim(data)[2]]
> colnames(geno) <- paste(seq(1, dim(geno)[2]))
> geno.obj <- SummarizedExperiment(geno)
> obj <- rqtClass(phenotype=pheno, genotype=geno.obj)
> res <- rQTest(obj, method="pca", out.type = "D")
> print(res)
```

Phenotype:

```
[1] 1 1 1 1 1 1
...
```

Genotype:

```
  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28
[1,] 0 0 0 1 0 2 1 0 0 0 2 1 2 0 0 2 1 1 0 0 1 0 0 0 2 1 0

### 3.4 Preprocessing with Partial Least Square regression (PLS)

This method is used for continous outcome, i.e. out.type = "C".

```

> library(rqt)
> data <- data.matrix(read.table(system.file("extdata/test.cont1.dat",
+                                           package="rqt"), header = TRUE))
> pheno <- data[,1]
> geno <- data[, 2:dim(data)[2]]
> colnames(geno) <- paste(seq(1, dim(geno)[2]))
> geno.obj <- SummarizedExperiment(geno)
> obj <- rqtClass(pheno=pheno, genotype=geno.obj)
> res <- rQTest(obj, method="pls", out.type = "C")
> print(res)

```

Phenotype:  
[1] 3.422452 2.457394 2.708564 4.589394 5.461723 4.438707  
...

```

Genotype:
      1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28
[1,]  0  0  0  1  0  2  1  0  0  0  2  1  2  0  0  2  1  1  0  0  1  0  0  0  0  2  1  0

### 3.6 Using additional covariates

Quite often, researchers want to supply not only genetic data but also specific covariates, representing some physiological parameters or environment (for example, to evaluate hypotheses of gene-environment interactions). In such cases, the package `rqt` can accept additional covariates, in form of N by K matrix, as provided below:

```

> library(rqt)
> data <- data.matrix(read.table(system.file("extdata/test.bin1.dat",
+                                           package="rqt"), header = TRUE))
> pheno <- data[,1]
> geno <- data[, 2:dim(data)[2]]
> colnames(geno) <- paste(seq(1, dim(geno)[2]))
> geno.obj <- SummarizedExperiment(geno)
> covars <- read.table(system.file("extdata/test.cova1.dat", package="rqt"),
+                         header=TRUE)
> obj <- rqtClass(phenotype=pheno, genotype=geno.obj, covariates = covars)
> res <- rQTTest(obj, method="pca", out.type = "D")
> print(res)

```

Phenotype:

```

[1] 1 1 1 1 1 1
...

```

Genotype:

```

      1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28
